Appendix	15

Executive Summary

As of May 2025, there are 137 described species of frogs that occur within South Africa. Including Data Deficient and Near Threatened, 33% of these are considered threatened according to our most recent assessments. 21% fall into the top threat categories (VU, EN, CR).

One of the tools in the species conservation toolbox is the *ex situ* management and breeding of threatened species. This supports the eventual reintroduction into suitable habitats, helping to restore populations in the wild.

The third Global Amphibian Assessment, which kicked off in April 2024 in Cape Town, South Africa, began with a joint assessment of the IUCN Red List Authority and AArk's Conservation Needs Assessments. While this included 10 countries and over 240 species evaluated, in this report, we present only the results from South Africa.

We identified six South African species that need *ex situ* conservation actions, including *ex situ* rescue, biobanking, and applied *ex situ* research.

Amphibian Ark

Rescuing amphibians in crisis

Amphibian Ark (AArk) is a non-profit organization founded in 2007 by the IUCN Species Survival Commission's (SSC) specialist groups: the Amphibian Specialist Group (ASG) and the Conservation Planning Specialist Group (CPSG), in partnership with the World Association of Zoos and Aquariums (WAZA).

Our mission is to rescue amphibians in crisis, saving species that cannot currently be safeguarded in nature. At AArk we work to secure a future for those amphibian species likely to become extinct before their natural environment can be made safe for them again. For those species, we help set up *ex situ* assurance programs so that when it is safe to do so, they can be released back into the wild.

We collaborate closely with our sister organizations: the IUCN SSC Amphibian Specialist Group (ASG) and the Amphibian Survival Alliance (ASA). Together, the three organizations aim to amplify amphibian conservation efforts around the world, to achieve our shared vision: amphibians thriving in nature.

The Conservation Needs Assessment process

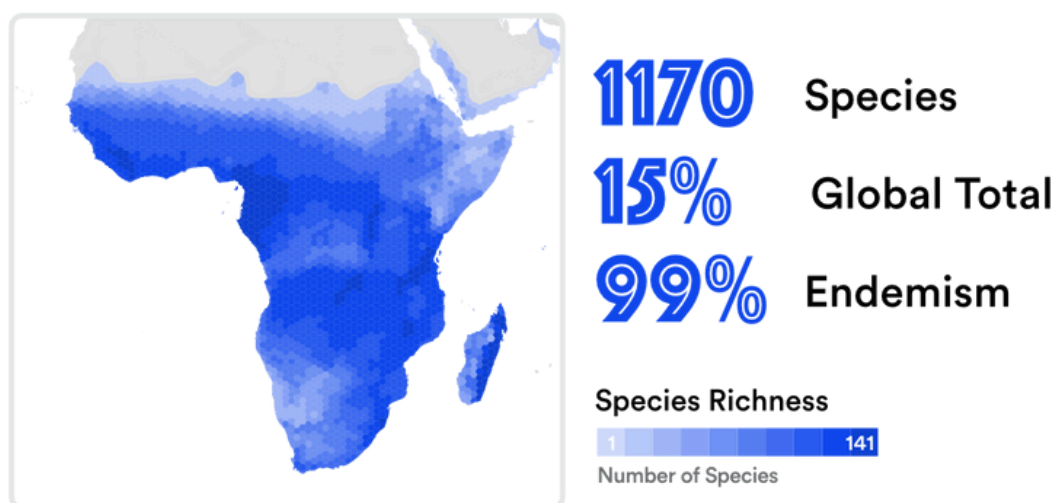

The Conservation Needs Assessment (CNA) process developed by AArk uses current knowledge of species in the wild to determine those with the most urgent conservation needs. It provides a basis for the development of holistic conservation action plans that combine *in situ* and *ex situ* actions, as appropriate. These assessments allow us to maximize the impact of limited conservation resources by identifying which measures could best serve those species that require assistance.

Amphibian Conservation Overview

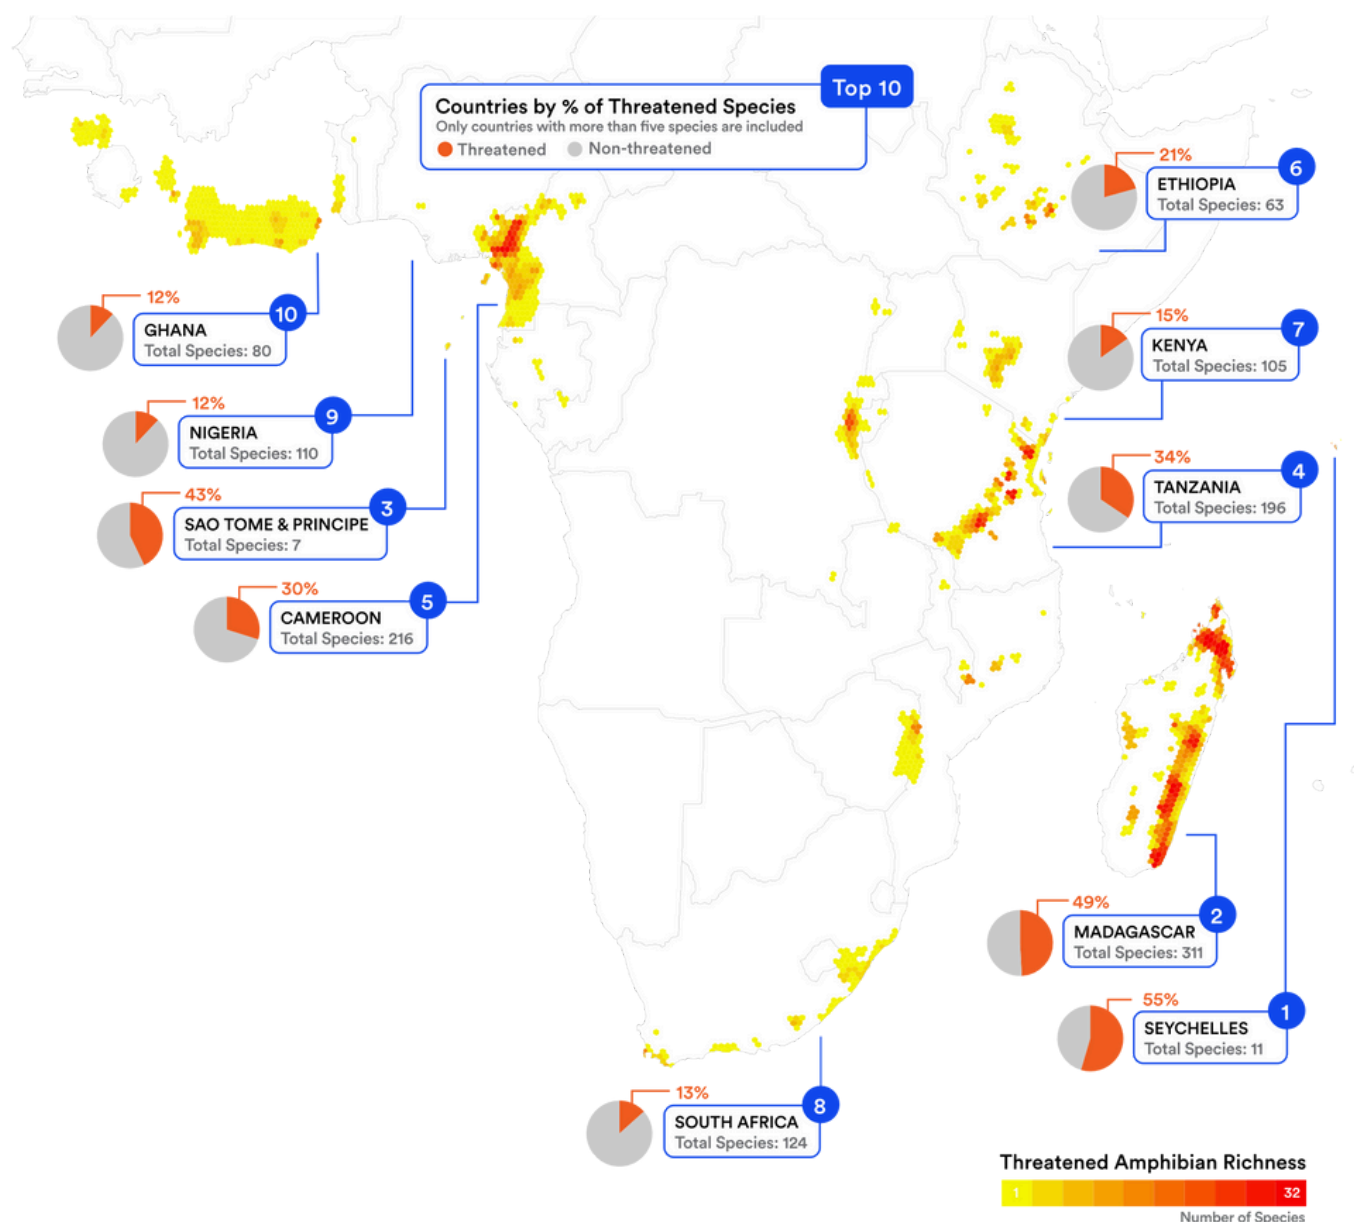

41% of amphibians—that is, two out of every five species—are threatened with extinction. This makes it the most endangered group of vertebrates worldwide. Out of the three groups that compose amphibians—frogs and toads, salamanders, and caecilians—salamanders are the most threatened (60%).

Amphibian species richness in the Afrotropics. Extracted from: Re:wild, Synchronicity Earth, IUCN SSC Amphibian Specialist Group. 2023. [State of the World's Amphibians: The Second Global Amphibian Assessment](#). Texas, USA: Re:wild

According to the 2023 [State of the World's Amphibians: The Second Global Amphibian Assessment](#), the Afrotropical realm has received less research effort compared to other realms, but “it is expected to be a treasure trove of amphibians”. As of May 2025, there are 137 described species of frogs that occur within South Africa. Including Data Deficient and Near Threatened, 33% of these are considered threatened according to our most recent assessments. 21% fall into the top threat categories (VU, EN, CR).

According to the State of the World's Amphibians (SOTWA), habitat loss and degradation are the main threats to amphibians and affect more than 2,600 (93%) of threatened species. Another major threat to amphibians is climate change. Amphibians are ectotherms with moist, highly permeable skin and depend on the availability of water to survive. Hence, they are particularly sensitive to changes in humidity and temperature. Climate change can also exacerbate other threats, such as fires, diseases, or invasive species, thus compounding the impacts.

Countries of Sub-Saharan Africa by percentage of threatened amphibian species. Extracted from:
Re:wild, Synchronicity Earth, IUCN SSC Amphibian Specialist Group. 2023. State of the World's Amphibians: The Second Global Amphibian Assessment. Texas, USA: Re:wild

There are several urgent actions we can take to help amphibians:

- Develop large-scale multi-institutional collaborations for amphibian research and protection.
- Establish environmental management practices that allow a more harmonious coexistence between amphibians, their habitats, and people.
- Establish or expand conservation breeding programs, incorporating biobanks and assisted reproduction technologies, to safeguard against extinction and allow future reintroductions and translocations.

Assessment Team

Conservation Needs Assessment workshop

The third Global Amphibian Assessment—which evaluates every known amphibian species for the IUCN Red List of Threatened Species—kicked off in April 2024 in Cape Town, South Africa. In early 2024, Amphibian Ark’s Program Director, Becca Brunner, joined the team of experts to conduct the Conservation Needs Assessments for these species as a joint assessment with the IUCN Red List Authority. This included 10 countries and over 100 species evaluated; in this report we present only the results from South Africa.

The results obtained in this workshop are summarized in this table:

Recommended Conservation Actions*	No. of species
Ark	0
Rescue	5
<i>In situ</i> conservation	25
<i>In situ</i> research	34
Husbandry research	4
Applied <i>ex situ</i> research	1
Mass production	0
Education	15
Supplementation	0
Biobank	5
None	1

*The explanation of each conservation action is described on the Appendix

Species recommended for *ex situ* actions

As mentioned before, AArk focuses its efforts on rescuing amphibians that cannot currently be safeguarded in the wild. We do this through supporting *ex situ* conservation programs, training, and assessments. Ideally, an *ex situ* initiative should be temporary and seen as only one of the tools that can assist in the conservation of a species. Therefore, strong links between *ex situ* and *in situ* components are critical to the long-term success of species conservation.

We identified six South African species that need *ex situ* conservation actions, including *ex situ* rescue (n = 5) and *ex situ* research (n = 1). Due to their level of threat, the five species recommended for *ex situ* rescue are also recommended for biobanking.

Vandijkophrynus amatolicus
© Joshua Weeber

Of the five species recommended for *ex situ* rescue, only *M. capensis* and *C. rosei* currently (1) have sufficient numbers of individuals in nature (in situ) that can be used as founders for the program, (2) are distinct biological units, and (3) have sufficient habitat available for reintroduction.

Microbatrachella capensis

Species recommended for *ex situ* rescue.

Distribution

Endemic to South Africa in the Western Cape Province

IUCN Global Red List: Endangered (EN) | Changed from CR to EN after this workshop

Assessment Summary: This species relies on lowland flooded areas, but most have been drained for development and agriculture; infestation of invasive trees, which dry out breeding pools, has also been rampant. Most populations are too fragmented for dispersal. *Ex situ* rescue will be essential for assisted translocations to restored protected habitat.

[Link to CNA Assessment.](#)

Capensibufo rosei

Species recommended for *ex situ* rescue.

Distribution

Endemic to the Cape Peninsula of South Africa

IUCN Global Red List: Critically Endangered (CR)

Assessment Summary: This species is only found in Table Mountain National Park, with potentially only 2 breeding areas remaining. 3 of the 5 subpopulations have already been lost, and one catastrophic event could wipe out the species. This species relies on fires to keep the vegetation levels low around shallow accumulations of water, but fires are actively suppressed by management. Vegetation (such as the invasive Pampas Grass) encroachment could completely wipe out their breeding habitat in a couple of years.

[Link to CNA Assessment](#)

B. macrops, *B. bagginsi*, and *V. amatolicus* are also recommended for *ex situ* rescue, but currently do not have enough habitat available for reintroduction.

Breviceps macrops

Species recommended for *ex situ* rescue.

Distribution

Western coast of South Africa and Namibia

IUCN Global Red List: was previously assessed as Near Threatened (NT). After this assessment has been assessed as Vulnerable (VU).

Assessment Summary: This species does not occur in any protected areas and is facing devastating habitat loss from multiple sources: coastal dune strip mining for diamonds, urbanization, large infrastructure development (namely the Boegoebaai Port and Rail Project), and a forthcoming hydrogen project. Rescue of individuals before these projects begin is of utmost importance if this species is to avoid extinction. Since members of this species spend most of their time buried under sand dunes, very little is known about their ecology. *Ex situ* research, specifically breeding moisture and soil depth requirements, will be necessary to increase the success of reintroductions, especially to restored dune sites post diamond mining/scraping.

[Link to CNA Assessment](#)

Breviceps bagginsi

Species recommended for *ex situ* rescue.

Distribution

South-eastern South Africa (Kwazulu-Natal midlands)

IUCN Global Red List: was previously assessed as Near Threatened (NT). After this assessment has been assessed as Critically Endangered (CR).

Assessment summary: Less than 1% of this species' range occurs within a protected area, and more than 75% of its habitat has been lost to land-use change, especially pine monoculture and urbanization. The few grassland habitat patches remaining are under threat from road development, cattle grazing, and fire. The species is projected to go extinct in less than 20 years without conservation intervention. *Ex situ* research on its breeding requirements (soil moisture and temperature) will be essential for this species, as its eggs and tadpoles develop in underground tunnels.

[Link to CNA Assessment](#)

Vandijkophrynus amatolicus

Species recommended for *ex situ* rescue.

Distribution

South Africa

IUCN Global Red List: Endangered (EN) | Changed from CR to EN after this workshop

Assessment summary: This species is known only from the Amathole Mountains in the Eastern Cape province, and currently, none of its range occurs within a protected area. The main threat to this species is loss and degradation of grassland and seepage habitat due to land-use change to non-native forest plantations and agricultural practices. Cattle stocking threatens the water quality of breeding seeps. If protected areas are not created and/or these threats are not mitigated, this species will likely disappear.

[Link to CNA Assessment](#)

Analog species

We also identified a species that could be good analog candidate for other species. Analog species are species with a lower degree of threat but with biological characteristics similar to those of the target species that require *ex situ* conservation. These analogous species are used to test and refine maintenance and reproduction protocols before applying them to the more threatened species, increasing the likelihood of success for the *ex situ* program.

Analog Species

Capensibufo selenophos

Target Species

Capensibufo rosei

Additionally, we identified *Breviceps adspersus* as a potential analog species for other *Breviceps* species that have a similar biology. However, there are still many unknowns about the biology and ecology of many species within this genus, and their habitats vary widely (e.g. desert, grassland). Until then, the real usefulness as an analog species remains unknown. As one step to better understand the biology of some of these species, the assessment team also identified both *B. macrops* and *B. bagginsi* as good candidates for *ex situ* research.

Species for conservation education programs

Finally, we identified 15 species for which conservation education programs are being carried out or are recommended to be carried out. This list is made up of species that are mostly colorful or that due to other characteristics are excellent candidates for the development of these programs.

Appendix

Conservation actions explained:

Note: one species can have more than one conservation action recommended.

Ark	A species that is extinct in the wild (locally and globally) and will become completely extinct without <i>ex situ</i> management.
Rescue	A species in imminent danger of extinction (locally or globally) which require <i>ex situ</i> management as part of a comprehensive conservation program to ensure their survival.
<i>In situ</i> conservation	A species for which effective mitigation of threats in nature and/or the creation of additional protected habitats is required as part of an integrated action plan to ensure successful survival and conservation.
<i>In situ</i> research	A species that requires further <i>in situ</i> research as part of conservation actions. At least one critical piece of information is still to be known.
Husbandry research	Species recommended as reproductive analogs of more threatened species that have been recommended for <i>ex situ</i> recovery. These species should be used to study and develop handling protocols that can be applied to more threatened species.
Applied <i>ex situ</i> research	Species recommended for <i>ex situ</i> research projects other than husbandry research, which directly contribute to the conservation of this species, or a related species, in the wild.

Conservation actions explained (cont.):

Mass production

A species threatened in the wild due to its collection (*e.g.* as a food source), which can be bred in captivity at this time—usually in the country of origin of the species—to meet the demand for special purposes that would otherwise imply collecting species from the wild. This category generally excludes breeding for pets, except in cases where the careful and coordinated breeding and handling can demonstrate reduced pressure of threatened species in the wild.

Education

Species selected for management with the purpose of inspiring visitors of zoos and aquariums, national parks, recreation areas and forests, and in ecotourism activities to increase their knowledge and promote behavioral change in people. For example, when a species is used to promote financial or other support for field conservation projects (including “flag” species or “ambassador species” that are clearly defined).

Supplementation

A species for which *ex situ* management would benefit wild populations through a breeding-and-release program as part of conservation action recommendations.

Biobank

Species for which storage of sperm or cells to perpetuate their genetic variation is urgently recommended due to the serious threat of extinction of the species.

None

Species that do not require any conservation action at this time.
